memorandum

DATE: SEP 25 1992

REPLY TO ATTN OF: EM-421 (W. A. Williams, 903-8149)

SUBJECT: Authorization for Remedial Action at B&T Metals in Columbus, Ohio

TO: L. Price, OR

The B&T Metals facility, located at 425 West Town Street in Columbus, Ohio, is hereby designated for inclusion in the Formerly Utilized Sites Remedial Action Program (FUSRAP). This designation is based on the results of a radiological survey and conclusions from an authority review as noted in the attached Designation Summary. Copies of the preliminary radiological survey report and authority determination are provided for information.

The site has been assigned a low priority under the FUSRAP protocol. The preliminary survey concluded that the property contains residual radioactivity in excess of current guidelines. However, the radioactivity is very localized and limited in extent, and under present conditions and use, no significant radiation exposures would occur to individuals who access the areas.

Because site contamination is limited, we recommend that cleanup of the site follow the expedited procedure now under development for remedial action at small sites. We will work closely with the designation contractor Oak Ridge National Laboratory, with the site owner, and with your staff to assure that remedial action is conducted efficiently.

The effect of this designation on the FUSRAP baseline should be evaluated, documented, and submitted for approval under the baseline change control procedures.

Designation Summary
The B&T Metals Company

INTRODUCTION

The Department of Energy (DOE), Office of Environmental Restoration, has reviewed the past activities of the Manhattan Engineer District (MED) at the B&T Metals Company in Columbus, Ohio, and has completed a preliminary radiological survey of the site (Cottrell, et al., 1990). DOE has determined that the residual radioactive materials inside the building exceed current guidelines (USDOE, 1987, 1990) for release of facilities to the general public without radiological restrictions. Results of outdoor soil sampling indicate the presence of some residual contamination that is higher than typical site-specific uranium guidelines for soil derived for similar DOE sites.

Based on a review of the available historical documentation and the results of the survey, the DOE has concluded that this site shall be designated for remedial action under the Formerly Utilized Sites Remedial Action Program (FUSRAP). The site has been assigned a low priority as the survey results indicate that the residual radioactivity is limited in extent and poses no immediate risk to workers. The remainder of this report summarizes the site information and the designation decision.

BACKGROUND

Site Function (Williams, 1991)

In February 1943, the DuPont Company, acting as an agent of the MED, contracted with B&T Metals to extrude rods from uranium metal billets. The rods were destined for the Hanford reactor. After initial test operations in February, production extrusion began in March 1943 and continued until August of that year. It is likely that in excess of 50 tons of uranium were extruded.

Health and safety protection was provided by Metallurgical Laboratories of the University of Chicago. Measurements taken in March and April 1943 indicated significant amounts of airborne material, and the extrusion process was modified to reduce debris. Upon completion of the project, MED and DuPont representatives visually inspected the site to verify that the facilities and equipment had been cleaned and that all sweepings, turnings, solid scrap, oxides and wet residue had been shipped elsewhere.

Site Description (Cottrell, et al., 1990)

B&T Metals is located at 425 West Town Street on the southwest side of Columbus, Ohio. The buildings and property cover most of a city block. The site consists of three buildings: (1) the main office, (2) a storage building, and (3) an extrusion building, which did not exist at the time of the MED-sponsored activities. The work performed for MED occurred in the northwest corner of the main office building, the largest of these three structures. Reportedly, shavings from these activities may have been dumped outside in what is now a parking area, west of the main office building. Machinery used for processing uranium has been sold or removed, with no records indicating final disposition.

Owner History

The site has been continuously owned and operated by the B&T Metals Company.

Radiological History and Status

As previously discussed, some industrial monitoring was performed during extrusion operations. However, there are no records of extensive surveys or decontamination.

A radiological assessment of soil and dust samples performed in 1989 (Cottrell, et al., 1990) measured concentrations of radium and thorium at or near the background level, and indoor air samples were below the minimum detectable amounts for gross alpha and beta radiation. However, direct beta-gamma measurements at floor and overhead beam locations exceeded the surface dose rate guideline. Concentrations of uranium ranging from 700 to 1700 picoCuries per gram have been identified inside the main office building in several floor, sump and drain locations and in dust on building support beams. Outdoor soil samples taken at locations with elevated gamma readings, corresponding to the area where shavings from the MED activities reportedly were dumped, showed uranium concentrations ranging from 3.5 to 110 picoCuries per gram. Areas of the site have residual radioactivity exceeding DOE guidelines for use without radiological restrictions (USDOE 1987, 1990).

Authority Review

In 1991, the DOE determined that it had the authority to conduct remedial action at the site (USDOE, 1986; Williams, 1991). This determination of authority under FUSRAP was based upon the following significant factors.

- Available records indicate that B&T was directly supervised by MED contractors and that MED staff were directly involved in the arrangements to use the facility.
- As a part of the operations at the site, there were strict requirements concerning security, accountability, health, and safety. These were controlled by MED or its prime contractors.
- The uranium machined at the site was owned by the government.
- MED staff visited the facility several times to address problems or review performance.

An earlier authority determination, dated October 28, 1985, found that DOE had authority to perform remedial action for a group of MED metal fabrication contractors, including B&T Metals. Since this earlier determination, DOE has surveyed the site and identified contaminated areas of the B&T Metals Facility.

DESIGNATION DETERMINATION

The results of the preliminary radiological survey indicate that contamination in excess of DOE guidelines exists in several localized areas inside the building. Elevated uranium levels were also recorded in one outside location, and the levels exceeded the site-specific levels typical of other FUSRAP sites. The survey report noted there is no current significant risk to workers or the general public from the residual contamination at the site.

The DOE has authority to conduct remedial action at the site under FUSRAP. This authority is based on prime contractor and MED use of the site and control of operations. Therefore, the site meets the criteria for designation (USDOE, 1986).

As current use of the site will not result in doses in excess of guidelines, and because potential health risk and spread of contamination are small, the site is designated a low priority site.

Research for this project was sponsored by the Division of Facility and Site Decommissioning Projects, U.S. Department of Energy, under Contract No. DE-AC05-84OR21400 with Martin Marietta Energy Systems, Inc. The authors wish to acknowledge the contributions of T. R. Stewart and D. A. Roberts of the Measurement Applications and Development Group for participation in the analyses and reporting of data for this survey.

ABSTRACT

As part of the Formerly Utilized Sites Remedial Action Program (FUSRAP), the U.S. Department of Energy (DOE) is implementing a radiological survey program to determine the radiological conditions at sites that were formerly used by the department's predecessor agencies. The preliminary radiological survey discussed in this report for the B&T Metals site in Columbus, Ohio, is part of the FUSRAP effort and was conducted at the request of DOE by members of the Measurement Applications and Development Group of Oak Ridge National Laboratory in 1988 and 1989.

In the 1940s the B&T Metals site was used to provide extrusion of uranium billets into rods in support of the Manhattan Engineer District (MED) operations. The preliminary radiological survey included a surface gamma scan, collection of dust, debris, and soil samples, measurement of direct and transferable alpha and beta-gamma activity, and air sampling. Results of this radiological assessment indicate that the property contains residual radioactivity from MED activities in concentrations that exceed remedial action guidelines.

RESULTS OF THE PRELIMINARY RADIOLOGICAL SURVEY AT B&T METALS, 425 WEST TOWN STREET, COLUMBUS, OHIO (CO001)*

INTRODUCTION

In 1942, under jurisdiction of the U.S. Army Corps of Engineers, the Manhattan Engineer District (MED) was established as the lead agency in the development of nuclear energy for military objectives. Although much of the government-sponsored research was centered at the national laboratories, commercial facilities were used for storage and processing of uranium and thorium ores and for fabricating and machining metal made from these ores. As a result of these activities, equipment, buildings, and land became contaminated with naturally occurring radioactive nuclides. These sites were later decontaminated in accordance with contemporary standards. However, subsequent radiological criteria, guidelines, and proposed guidelines have become more stringent for the release of such sites for unrestricted use, and records documenting decontamination are sometimes not adequate for determining final radiological conditions. Thus, the Formerly Utilized Sites Remedial Action Program (FUSRAP) was initiated to identify these sites and to reevaluate their radiological status.[1] The preliminary radiological survey discussed in this report for the B&T Metals site in Columbus, Ohio, is part of the FUSRAP effort and was conducted, at the request of DOE, by members of the Measurement Applications and Development Group of Oak Ridge National Laboratory (ORNL).

In the mid-1940s B&T Metals became one of the first commercial firms to provide extrusion of uranium billets into rods in support of the MED operations. The extrusion and machining activities were relatively small scale and occurred over a period of approximately ten months.

B&T Metals is located at 425 West Town Street on the southwest side of Columbus, Ohio. The buildings and property cover most of a city block (Fig. 1). The site consists of three buildings: (1) the main office, (2) a storage building, and (3) an extrusion building, which did not exist at the time of the MED-sponsored activities (Fig. 2). The work performed for MED occurred in the northwest corner of the main office building, the largest of these three structures. Reportedly, shavings from these activities may have been dumped outside in what is now a parking area, west of the main office building (Fig. 3).[2] Machinery used for processing uranium has been sold or removed, with no records indicating final disposition. A review of the records indicated that part of the extrusion and machining process involved "blowing out" the heating cylinders on the extrusion press. This resulted in large quantities of uranium-bearing material being blown

*The survey was performed by members of the Measurement Applications and Development Group of the Health and Safety Research Division at Oak Ridge National Laboratory under DOE contract DE-AC05-84OR21400.

into the room. Measurements taken in March and April of 1943 confirmed excessive amounts of airborne metals found near the rolling table, extrusion trough, and furnace. Appropriate recommendations were made to B&T Metals that this practice be discontinued.[3]

An initial screening survey of the commercial property, B&T Metals, 425 West Town Street, Columbus, Ohio, was conducted by members of ORNL's Measurement Applications and Development Group on August 22, 1988. A subsequent visit was made to the site on April 25, 1989, to collect air samples in the main office building.

SURVEY METHODS

The preliminary radiological survey included (1) a gamma scan at the surface of the main office building and at the surface of most of the property outdoors; (2) collection of dust and debris samples from the floor and from overhead beams in the main office building; (3) collection of surface soil samples; (4) measurement of direct and transferable alpha and beta-gamma activity levels inside and on the roof of the main office building; and (5) air sampling of the main office building.

Using a portable gamma scintillation meter, ranges of measurements were recorded inside the main office building and for areas of the property surface outdoors. Alpha and beta-gamma activity measurements were taken at selected surface locations in the main office building, on the structural support beams, and on the roof. Smears of 100-cm^2 areas were also obtained to establish transferable alpha and beta-gamma activity levels.

Samples of dust were collected from the beams in the area where MED operations were reported to have taken place. Biased soil samples were taken at locations with elevated gamma readings.

For convenience in defining areas to be surveyed, the main office building was divided into 6.1-m (20-ft) blocks, with the northwest corner of the building used as the origin (0,0) (Fig. 4). The survey methods followed the plan outlined in Reference 4. A comprehensive description of the survey methods and instrumentation has been presented in another report.[5]

SURVEY RESULTS

Applicable DOE residential guidelines for protection against radiation are summarized in Table 1.[6] Normal background radiation levels for the Columbus, Ohio, area are presented in Table 2.[7] These data are provided for comparison with survey results presented in this section. With the exception of measurements of transferable radioactivity, which are reported as net disintegrations rates, all direct measurement results presented in this report are gross readings; background radiation levels have not been subtracted. Similarly, background concentrations have not been subtracted from radionuclide concentrations in soil samples.

Indoor Survey Results

Gamma Radiation Levels

Surface gamma exposure levels measured on the floor of the main office building generally ranged from 6 to 12 μR/h, with the higher levels occurring near brick walls. By comparison, the Columbus, Ohio, area background ranges from 7 to 9 μR/h (Table 2). Because the raw materials used to make bricks frequently contain small amounts of naturally occurring radioactive substances, the finished product may exhibit slightly higher-than-background gamma levels.

Three areas in the northwest corner of the main office building (the site of the former MED activities) had gamma radiation measurements higher than 12 μR/h (Fig. 4). A crack in the concrete floor showed a gamma level of 14 μR/h. A depression in the floor, filled with a tarlike substance, measured 16 μR/h gamma, and a sump approximately 0.3 × 0.9 m (1 × 3 ft) had gamma levels of 10-50 μR/h. A sample of material from this sump was collected and analyzed for radionuclide content (Table 3, sample B2).

Roof drains from the main office building are routed from the roof to the inside of the building, where the drains apparently enter the storm-drain system beneath the floor. A cleanout plug was removed from one of these vertical drains, and gamma radiation levels of 30 μR/h were measured 0.6 to 0.9 m (2 to 3 ft) below the floor surface. These measurements indicate a significant possibility that residual radioactive materials are in the drain system, probably resulting from materials being washed from the roof and/or the floor of the building.

Alpha and Beta-Gamma Measurements

Direct alpha and beta-gamma measurements were taken at 10 locations inside the main office building (three on the floor and seven on overhead beams). These measurements and the locations are given in Table 4. Direct alpha measurements were below DOE guidelines. Direct beta-gamma measurements at the three floor locations were 0.66 mrad/h for the crack, 0.81 mrad/h for the depression, and 3.9 mrad/h for the sump (Fig. 4). These values exceed the surface dose rate guideline of 0.2 mrad/h averaged over not more than 1 m^2 (Table 1). Three of the seven overhead beam locations (Figs. 4 and 5) exceeded the 1.0 mrad/h maximum dose rate for a 100-cm^2 area. Values and locations (Fig. 4) are 1.1 mrad/h (10S, 10E), 1.5 mrad/h (20S, 10E), and 2.5 mrad/h (22S, 40E). At location 50S, 40E a measurement was taken over the dust layer on the support beam; then the dust layer was removed and another measurement was taken. With the dust intact, the measurements were 530 dpm alpha and 0.61 mrad/h beta-gamma. Following removal of the dust, the measurements dropped to 470 dpm alpha and 0.069 mrad/h beta-gamma, indicating residual radioactivity in the dust. Samples of this dust were collected for radionuclide analyses.

Thirty-three measurements of direct and transferable radioactivity levels were taken on the roof of the main office building. On the inclined portion of the sawtooth roof (Fig. 6), 29 measurements were taken, and 4 measurements were taken on the level roof of the first-floor annex. Measurements are shown in Table 5. Locations are shown in Fig. 7 (referenced to Fig. 4). All direct alpha measurements are well below DOE guidelines for fixed uranium concentration (Table 1). One direct beta-gamma measurement (location 20S, 2E) was 0.20 mrad/h. Other direct beta-gamma measurements were well below the guideline for surface dose rate averaged over an area ≤ 1 m^2.

Smear samples were obtained from the roof locations at which direct measurements were taken. Analyses of the smears showed all measurements of transferable alpha and beta-gamma radiation well below DOE guidelines for removable uranium (Table 1).

Dust and Debris Samples

Inside the main office building, samples were collected from locations showing elevated gamma measurements, and these samples were analyzed for radionuclide concentrations. Two dust samples from overhead beams, one tar sample from the floor, and one debris sample from a sump in the floor were analyzed. Results of these analyses are given in Table 3, and locations are shown on Fig. 4. Concentrations of ^{226}Ra and ^{232}Th were within typical background soil concentration ranges for the Columbus, Ohio, area (Table 2). Concentration of ^{238}U ranged from 700 to 1700 pCi/g. These values are above typical site-specific uranium guidelines for soil, derived for similar DOE FUSRAP sites (35-150 pCi/g). Concentration limits for uranium at FUSRAP remedial action sites are derived in accordance with DOE guidelines. The process ensures that doses to individuals using the sites are well below the 100 mrem/yr dose limit.

Air Samples

Sixteen air samples were taken from the main office building and analyzed for gross alpha radiation. All samples were below the minimum detectable amount of 1.5×10^{-13} μCi/cm^3 (0.5% of the maximum permissible concentration in air for ^{238}U).[8]

Outdoor Survey Results

Gamma Radiation Levels

Gamma exposure rates measured during a scan of the surface of the property outdoors are shown in Fig. 8. Over the major portion of the property, gamma radiation levels ranged from 7 to 12 μR/h, with measurements of 14 μR/h noted at the brick road behind the main office building, in the grassy area at the front of the building, and in the area west of the building, near the storage building. In the area west of the main office building, where shavings from the MED activities reportedly were dumped, surface gamma exposure rates were 40 and 50 μR/h at sample locations B10 and B9, respectively (Fig. 8).

Soil Samples

Biased soil samples were taken from three locations with elevated gamma readings and were analyzed for radionuclide concentrations. Locations of the biased (B) samples are shown on Fig. 8. Results of laboratory analyses for ^{226}Ra, ^{232}Th, and ^{238}U are shown in Table 6. Concentrations of ^{226}Ra and ^{232}Th ranged from 1.4 to 2.1 pCi/g and 0.63 to 1.3 pCi/g, respectively. These values are at or near background soil concentrations for the Columbus, Ohio, area (Table 2) and are well within the DOE guidelines shown in Table 1. Concentration of ^{238}U ranged from 3.5 to 110 pCi/g, with the higher concentrations (67 to 110 pCi/g) found in the two samples (B9 and B10) taken from the area where contaminated shavings were reportedly dumped. These values are higher than typical site-specific uranium guidelines for soil, derived for similar DOE FUSRAP sites.

SIGNIFICANCE OF FINDINGS

Radiological assessment of soil and dust samples from B&T Metals, Columbus, Ohio, demonstrated low concentrations of ^{226}Ra and ^{232}Th. Concentrations of ^{238}U ranged from 3.5 to 1700 pCi/g in the eight soil and dust samples analyzed. Areas containing residual radioactive material include:

1. three floor locations in the main office building (Fig. 4, locations 3S, 10E; 20S, 20E; and 40S, 40E) (see also Table 4);
2. the drain system beneath the floor of the main office building;
3. the support beams in the main office building (Table 4), where the source of the residual radioactive material appears to be dust from the former uranium extrusion process; and
4. one area outdoors (east of the storage building) where shavings from the former MED operations were reportedly dumped (Fig. 8, locations B9 and B10).

Direct beta-gamma measurements taken inside the main office building were in excess of the surface dose rate for the three floor locations given in Table 4, and in excess of the maximum dose rate in any 100-cm^2 area for three of the overhead beam locations. Results of this radiological assessment indicate that the property contains residual radioactivity from MED activities in concentrations that exceed remedial action guidelines. However, these conservative guidelines are based on possible exposure through inhalation, ingestion, or direct contact, and are typically derived to ensure that unrestricted use (including residential use) will not result in above-guideline doses to the general public. The residual radioactivity at the B&T Metals site is very localized and limited in extent, and an examination of present-use conditions for this site suggests that no significant radiation exposures would accrue to individuals who access the areas.

B4	20S, 20E, Overhead beam	<1.1	<1.6	1700 ± 50
B5	20S, 10E, Overhead beam	<0.96	<1.2	1200 ± 20

[a]Locations are shown on Fig. 4.

[b]Indicated counting error is at the 95% confidence level (± 2σ).

[c]These biased samples were taken from areas with elevated alpha and beta-gamma measurements.

[d]A tar sample taken from a depression in the floor of the main office building.

[e]Debris from a floor sump in the main office building.

Table 4. Direct alpha and beta-gamma measurements taken inside the main office building, B&T Metals, 425 West Town Street, Columbus, Ohio (CO001)

Location[a]	Direct measurements: Alpha (dpm/100 cm²)	Direct measurements: Beta gamma (mrad/h)	Description of location
		Floor	
3S, 10E	50	0.66	Floor, crack in concrete slab, ~ 3.8 cm x 1.1 m (~ 1.5 in. x 3.5 ft)
20S, 20E	<25[b]	0.81	Hole in floor, ~ 0.3 x 0.9 m (~ 1 x 3 ft), at drain pipe
40S, 40E	350	3.9	Floor
		Overhead beams	
10S, 10E	[c]	1.1	Wooden beam
20S, 10E	[c]	1.5	Beam near electric transformer
20S, 120E	40	0.16	Beam over platform at east end of anodizing area
22S, 40E	50	2.5	Beam extending over floor area 40S, 40E
50S, 40E	530	0.61	Beam extending over floor area 40S, 40E; measurement taken over dust layer
50S, 40E	470	0.069	Beam extending over floor area 40S, 40E; measurement taken after dust layer was removed
50S, 80E	50	0.29	Beam, ~ 3.7 m (~12 ft) high

[a]Locations are shown on Fig. 4.
[b]Minimum detectable activity level = 25 dpm/100 cm².
[c]Not taken.

Table 5. Systematic roof measurements taken at B&T Metals, 425 West Town Street, Columbus, Ohio (CO001)

Table 5 (continued)

Location[a]	Direct measurements		Transferable radioactivity[c]	
	Alpha[b] (dpm/100 cm^2)	Beta gamma (mrad/h)	Alpha[d] (dpm/100 cm^2)	Beta gamma[e] (dpm/100 cm^2)
60S, 60E	60	0.070	<10	<200
60S, 120E	<25	0.038	<10	<200
1	160	0.047	<10	<200
2	100	0.052	<10	<200
3	140	0.053	<10	<200
4	100	0.044	<10	<200

[a]Locations are shown on Fig. 7.

[b]Minimum detectable activity (MDA) level = 25 dpm/100 cm^2.

[c]Measurements of transferable radioactivity are net disintegration rates. Background radiation levels have been subtracted.

[d]MDA = 10 dpm/100 cm^2.

[e]MDA = 200 dpm/100 cm^2.

[f]Not taken.

Table 6. Concentrations of radionuclides in soil samples from B&T Metals, 425 West Town Street, Columbus, Ohio (CO001)

Sample ID[a]	Depth (cm)	Radionuclide concentration (pCi/g)[b]		
		^{226}Ra	^{232}Th	^{238}U
		Biased samples[c]		
B8	0–7.6	2.1 ± 0.02	1.3 ± 0.02	3.5 ± 0.5
B9A	0–7.6	1.4 ± 0.04	0.63 ± 0.06	110 ± 2
B9B	7.6–13	1.8 ± 0.01	1.0 ± 0.02	110 ± 0.8
B10A	0–7.6	1.4 ± 0.03	0.71 ± 0.04	89 ± 2
B10B	7.6–15	2.0 ± 0.03	1.1 ± 0.06	67 ± 3

[a]Locations are shown on Fig. 8.
[b]Indicated counting error is at the 95% confidence level (± 2σ).
[c]Biased samples are taken from areas shown to have elevated gamma exposure rates.
